### **Field Review**

The view of each one of the proposed Project scenarios was simulated in accordance with the weather and time of day variables set forth in the Solicitation Requirements. From a near, representative coastline key observation point (KOP), the view of the Project was simulated assuming clear, partly cloudy, and overcast conditions during early morning, midafternoon, and late day, as well as one night time simulation with the turbines lit under clear conditions. Ten simulations from the same KOP were completed for the S, M, and L scenarios for a total of 30 simulations. Ten simulations from two different KOPs were completed for the XL scenario for a total of 20 simulations.

At both of the KOPs identified for the required visibility study, a trained field crew from Atlantic Shores visual resources consultant, selected an appropriate photo location based on the availability of an open view toward the Project Area, appropriate composition, lighting, and, if possible, the inclusion of distinctive foreground features that allow recognition of the viewpoint by the public. At each viewpoint, a series of overlapping photos of the entire visible seascape was obtained in five-degree increments. A tripod-mounted, full frame digital single lens reflex (SLR) camera with a resolution of 30.4 megapixels and a 50-millimeter lens was used for all photos. This focal length is the standard used in visual simulations because it most closely approximates normal human perception of spatial relationships and scale in the landscape. Additionally, high-resolution video was taken at each of the simulated KOPs for use in video animations demonstrating the WTGs and environment in motion.

For views lacking background alignment features (i.e., identifiable landscape features with known locations), the field crew also utilized global positioning system (GPS) equipment with sub-meter accuracy to document the location of each KOP and foreground reference features (e.g., buildings, fences, flag poles, placed flags) visible in the photos. Precise locations of these features allow accurate camera alignment during the development of visual simulations. It also assures that the resulting simulations have a high degree of accuracy in terms of wind turbine generator (WTG) location and perceived size relative to other landscape features.

KOPs were photographed from recognizable locations that were also the most geographically proximate to the proposed WTGs. The location of the KOP relative to the WTG layouts is provided in Appendixes 9-4, 9-5, 9-6, and 9-7 (Visual Simulations). In addition to being the closest onshore location to the proposed Project scenarios, the selected KOPs also represent visual resources found within the City of Atlantic Shores and the Borough of Ship Bottom on Long Beach Island.

### **Visual Simulations**

To show anticipated visual changes associated with the proposed Project, high-resolution, georeferenced, three dimensional models (3D) were used to create realistic photographic simulations of the Project for each of the selected

### Appendix PUBLIC COPY

KOPs. The photographic simulations were developed by constructing a 3D computer model of the proposed WTGs, Project layout, design specifications and coordinates provided by Atlantic Shores Offshore Wind. A hypothetical WTG model using the largest dimensions under consideration was prepared.

Simulations were created by aligning each photographic viewpoint through a virtual 3D camera, using digitized location data for elements visible in the photograph. This step involves utilizing aerial photographs and GPS data collected in the field to create an AutoCAD® drawing. The 3D AutoCAD data were then imported into 3DS Max®, and additional components (cameras, modeled scene, etc.) were added. These data were superimposed over photographs as seen through the virtual camera from each of the viewpoints, and minor camera changes (height, roll, bearing) were made as necessary to align all known reference points within the view. This process ensures that Project elements are shown in proportion, perspective, and proper relation to the existing landscape elements in the view. Consequently, the alignment, elevation, dimensions, and scale of the modeled Project components are accurate and true in their relationship to other landscape elements in each photo.

The next step involves positioning the Project layout in each of the aligned views at the appropriate distance in front of, at, or below the horizon (depending on the distance from the viewer and curvature of the earth). This was done by first determining the distance to the horizon (ocean/ sky interface) visible in the photograph. This is accomplished by entering the viewer position and elevation into the Haversine Formula, which uses the radius of the earth (corrected for refraction)<sup>1</sup> to calculate the mathematical distance to the horizon, or the point at which the sky meets the water. This distance is then used to draw a horizontal line (virtual horizon) in the 3D model representing the mathematical horizon line, which is visible through the virtual camera. The virtual horizon is then precisely aligned to the visible horizon aligned to the photographed horizon, the positions of the individual WTGs were all placed relative to this horizon line. The Haversine Formula was then used to determine each turbine's position, relative to the horizon. For example, if the WTG appears in front of the horizon, the returned value is zero and the WTG will be placed at the horizon. If the WTG appears behind the visible horizon, the returned value will be a negative number. This value was then applied to the turbine's vertical position in the model so that it appears on or below the visible horizon.

At this point, a "wire frame" model of the WTGs and known reference points are shown on each of the photographs. The proposed exterior color/finish of the WTGs was then added to the model, and the appropriate sun angle was simulated based on the specific date, time, and location at which each photo was taken. This information allows the computer to accurately illustrate highlights, shading, and shadows for each individual WTG. All simulations show the WTGs with rotors oriented toward the southwest, which is generally the prevailing wind direction in the area. The simulations show a field of view of 38.7 degrees, which is equivalent to the field of view of a standard 50 mm camera lens.

To prepare nighttime simulations, **Sector** obtained data on the proposed aviation obstruction warning lights from the FAA Advisory Circular 70/7460-1L and the *Draft Proposed Guidelines for Providing Information on Lighting and Marking of Structures Supporting Renewable Energy Development* (BOEM, 2019) which set guidelines for the lighting of WTGs (FAA, 2016). Computer modeling and camera alignment for the nighttime photos were conducted in the same manner described for the daytime simulations. It was assumed that all lights will flash in a synchronized manner, as currently set forth by FAA guidelines. Nighttime simulations therefore show all WTGs with their lights on.

<sup>1</sup> Refraction values assume "typical" viewing conditions and do not account for atmospheric anomalies such as the mirage effect which is typically rare and of short duration but may temporarily increase turbine visibility.

### Visual Impact Assessment

The Bureau of Ocean Energy Management (BOEM) requires that Atlantic Shores Offshore Wind complete a comprehensive assessment of onshore resources that may be impacted by the Project. This assessment is known as Visual Impact Assessment (VIA). The study will:

- Describe the appearance of the visible components of the proposed Project.
- Define the character and visual quality of the landscapes within the Project's Visual Study Area (VSA).
- Define the types and sensitivity of viewer groups within the VSA.
- Inventory existing visually sensitive public resources within the VSA.
- Evaluate potential Project visibility within the VSA.
- Identify key observation points (KOPs) for visual assessment.
- Illustrate what the Project will look like from representative key observation points (KOPs).
- Assesses the visual impacts associated with the proposed Project.

The VIA will be included in the Project Construction and Operations Plan (COP) which will be available for public consumption and comment during the planning and permitting phase of the Project.

### Air Emissions Calculation Methodology

*"Explicit listing of foundations, assumptions, and conditions used in the quantification and monetization of environmental impacts"* 

This Appendix presents a description of how the "direct" emissions<sup>1</sup> of the Project, as reported in the Application Form, were calculated, including all assumptions used in preparing estimates of direct emissions. As described in Section 9, the emissions reported in the Application Form are predominantly from internal combustion engines<sup>2</sup>, and are quantified using a three-step process:

- 1. Detailed plans for each Project activity.
- 2. Load factors.
- 3. Emission factors.

Air emissions are broadly calculated as the product of engine rated capacity, hours operating, load factor, and emission factor.

### Plans for each project activity

<sup>1</sup> The project has no emissions directly caused by the generation of electricity. These calculations present emissions associated with construction, operation & maintenance, and similar supporting activities.
<sup>2</sup> Helicopters and certain other vessels may be powered by turbines instead of engines, but the calculation methodology is unchanged.
